

WEBINAR:

Using milk data to drive production & reproduction

PART 2

Presented by SHAUN BALEMI

DISCLAIMER: This is general information and only intended to create discussion and further investigation.

1. OVERVIEW of milk data

2. RESEARCH around milk data and reproduction

3. EXAMPLES of how we translate these insights into practical steps farmers can put in place

Kg/MS per cow is critical when reading milk component percentages, higher production = lower components

FAT% gives us an indication of rumen stability/performance

PROTEIN% gives us an indication of energy, AA supply and appetite

LACTOSE% gives us an indication of milk production potential

MILK UREA gives us an indication of protein supply, rumen protein utilisation and efficiency

Strong genetic influences however:

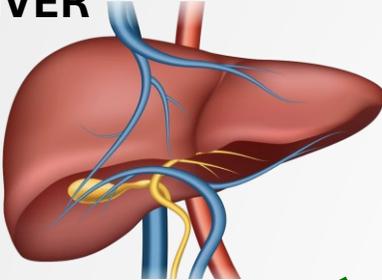

JERSEY = Higher fat%, lower protein% & lactose%

HOLSTEIN = Lower fat%, higher protein% & lactose%

Cow Breed (Live-Weight)	Jersey (400kg)	Kiwi-Cross (450kg)	Friesian (500kg)	Holstein (550kg+)
Peak Milk (MS/cow)	2.1kg	2.2kg	2.4kg	2.6kg
Fat%	5.6%	5%	4.7%	4.4%
Protein%	4.4%	4%	3.9%	3.7%
Protein:Fat Ratio	0.79 (0.78-0.82)	0.8 (0.79-0.83)	0.83 (0.80-0.84)	0.84 (0.81-0.85)
Milk Urea Nitrogen	22-28	24-30	26-32	28-34
Rumination (mins) ???	400+??	440+??	480+??	520+??
Activity (Eating mins) ???	380+??	420+??	460+??	500+??

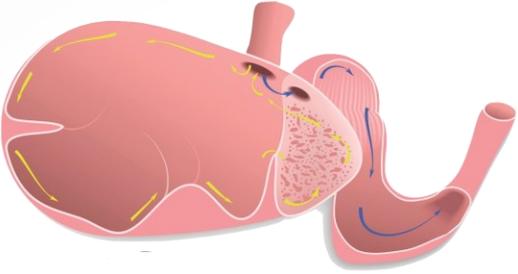

Combination of published & collected NZ Data, verified independently

LIVER

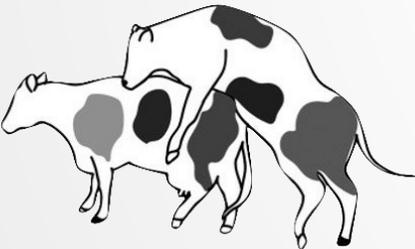

PROTEIN%

RUMEN

Protein:Fat
Ratio

FAT%
MILK UREA

- STABILISE THE RUMEN ENVIRONMENT!
- Increase EffNDF/fibre
- Pre-grazing residual
- Manage rumen flow rate
- Look at DM% in the pasture
- Rumen buffer/live yeast
- Balance acetate, butyrate, propionate

- Drive the rumen and liver engines harder!
- Increase rumen grunt/microbial population intensity
- This is done by feeding a better balanced, punchier feed
- Increase energy density
- Focus on protein balance: NPN/RDP/UDP/AAs
- Protein% runs closely alongside lactose%
- Look at rumen flow rates also, is the digesta in the rumen long enough for efficient microbial digestion?
- Live Yeasts? Methionine? Betaine?

- Increase feed quality/energy density
- Increase amino acid supply
- Increase appetite/intakes

To increase protein:fat ratio we need to increase protein%

BUT ensure rumen degradable protein (RDP) is sufficient, otherwise energy will leak out of the protein hole in the bucket!

Ensure fat% is optimum or ideal range is FALSE

Too low (<0.78) – energy potentially lacking

Too high (>0.85) – rumen instability/hot diet

INDICATES

- How hot the fire is! High lactose% = greater milk vol
- Feed conversion efficiency (FCE) & diet consistency
- Animal health issues: Udder inflammation, metabolic disorder/ketosis
- Higher lactose% is correlated to reproductive success

Lactose% is driven by energy, particularly glucose supply

Therefore, like protein%, lactose% is linked to feed quality and appetite

KNOW YOUR ENEMY!

- Herbage testing the feed to establish crude protein (CP) and non-protein nitrogen (NPN) levels
- Are we dealing with excess or lack of nitrogen/rumen degradable protein (RDP), or a lack of energy/starch/soluble sugar?
- RDP = Ammonia, peptides and amino acids - are we dealing with an imbalance?
- Metabolic shifts/subclinical ketosis will also drive up milk urea for a short period

TRANSITION – STRONG APPETITE – NEB – MINIMAL CONDITION LOSS Wathes et al., 2007

NEB influences protein:fat ratio – Insulin-like growth factor Negussie et al., 2013, Toni et al., 2011, Cbezaas-Garcia et al., 2021

Morton et al., 2017 & Martinez-Castillero et al. (2021)

Found a positive correlation between milk protein% and reproductive success

Carty et al., 2020

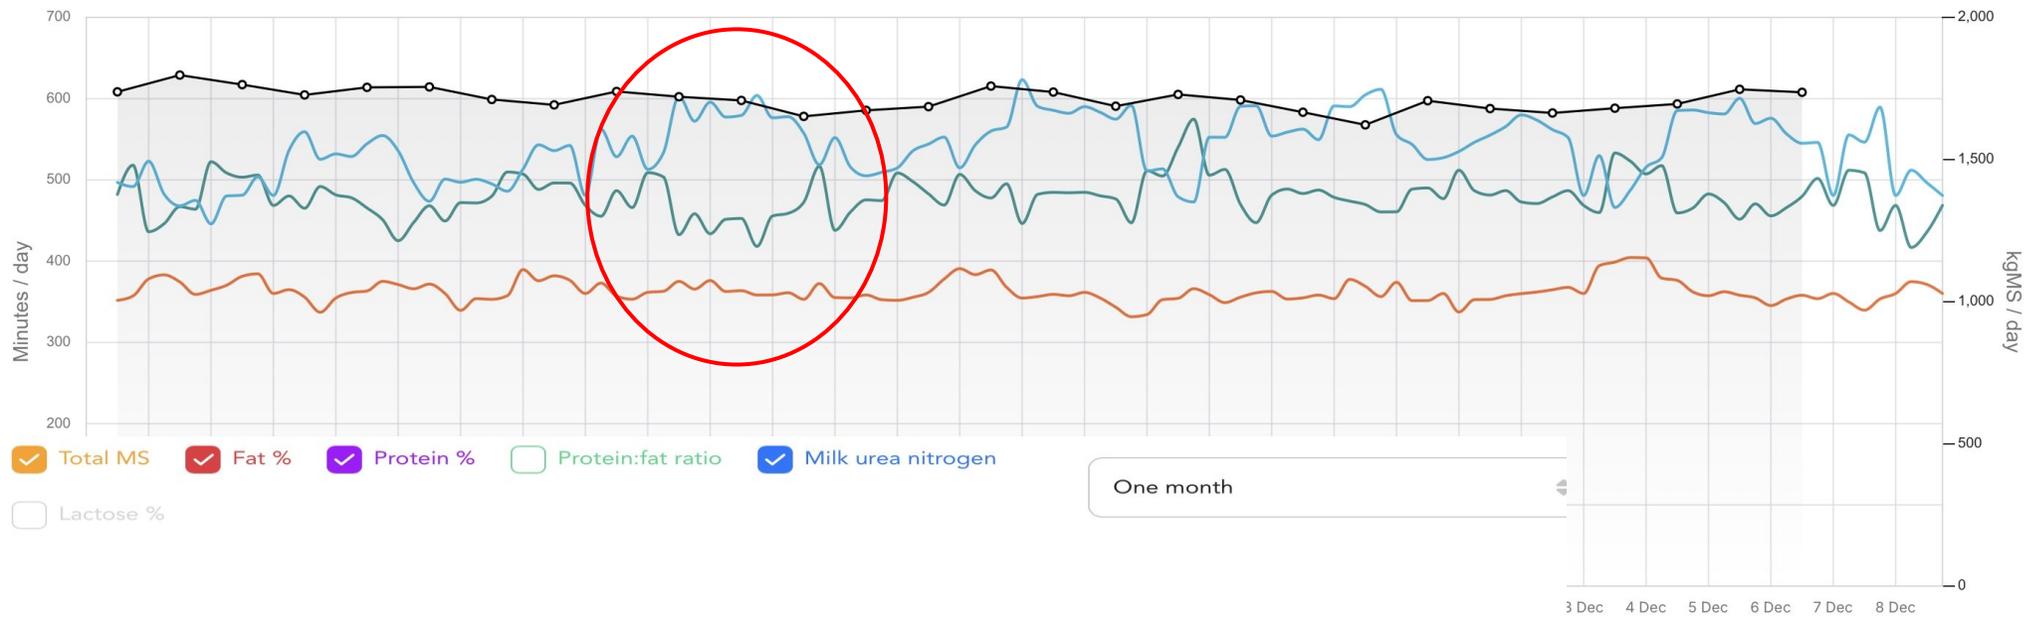

Found that cows with lower milk lactose% had, on average, 10 days longer to first cycle

Don't just look at %, the total kg of protein and lactose is also important as cow numbers are changing and DIM are increasing.
